A1

The following is the built-in **humps** function that MATLAB uses to demonstrate some of its numerical capabilities:

$$f(x) = \frac{1}{(x-0.3)^2 + 0.01} + \frac{1}{(x-0.9)^2 + 0.04} - 6$$

The **humps** function exhibits both flat and steep regions over a relatively short  $x$  range. Here are some values that have been generated at intervals of 0.1 over the range from  $x = 0$  to 1:

|        |       |        |        |      |        |     |
|--------|-------|--------|--------|------|--------|-----|
| $x$    | 0     | 0.1    | 0.2    | 0.3  | 0.4    | 0.5 |
| $f(x)$ | 5.176 | 15.471 | 45.887 | 96.5 | 47.448 | 19  |

|        |        |        |        |        |    |  |
|--------|--------|--------|--------|--------|----|--|
| $x$    | 0.6    | 0.7    | 0.8    | 0.9    | 1  |  |
| $f(x)$ | 11.692 | 12.382 | 17.846 | 21.703 | 16 |  |

Fit these data with a cubic spline with not-a-knot end Conditions

1. #35 p185-194, Atkinson

Consider finding a cubic spline interpolating function for the data

|     |     |     |     |      |     |     |
|-----|-----|-----|-----|------|-----|-----|
| $x$ | 0   | 1   | 2   | 2.5  | 3   | 4   |
| $y$ | 1.4 | 0.6 | 1.0 | 0.65 | 0.6 | 1.0 |

Use the "not-a-knot" condition to obtain boundary conditions supplementing (3.7.19). Graph the resulting function  $s(x)$ . Compare it to the use of piecewise linear interpolation, connecting the successive points  $(x_i, y_i)$  by line segments.

2. For the data given below,

|     |      |      |      |      |      |      |      |      |      |
|-----|------|------|------|------|------|------|------|------|------|
| $x$ | 0.1  | 0.2  | 0.4  | 0.6  | 0.9  | 1.3  | 1.5  | 1.7  | 1.8  |
| $y$ | 0.75 | 1.25 | 1.45 | 1.25 | 0.85 | 0.55 | 0.35 | 0.28 | 0.18 |

consider regression using the following nonlinear model:

$$y = \alpha x e^{\beta x}$$

You can linearize this function by first defining  $z$  as

$$z = y/x$$

then taking logarithm

$$\ln(z) = \ln(\alpha) + \beta x$$

Now you are ready to fit the data using the above linear function.

Your job: determine  $\alpha$  and  $\beta$ .

Develop a plot of your fit along with the data.

3. (Least square fit) In many applications, one wishes to correlate a dependent variable  $z$  to two or more independent variables,  $x$  and  $y$ . The simplest model is a linear fit

$$z = a_0 + a_1x + a_2y$$

Defining  $z_i - (a_0 + a_1x_i + a_2y_i)$  as the residual, one can determine the “best” values of the coefficients ( $a_0, a_1, a_2$ ) by minimizing the sum of the square of the residuals,

$$E_2 = \sum_{i=1}^n (z_i - a_0 - a_1x_i - a_2y_i)^2$$

where  $n$  is the total number of the data available for fitting.

a) Derive a 3x3 system of equations for ( $a_0, a_1, a_2$ ).

b) The following data was given. Find the linear fit for the data

| $x$ | $y$ | $z$ |
|-----|-----|-----|
| 0   | 0   | 5   |
| 2   | 1   | 10  |
| 2.5 | 2   | 9   |
| 1   | 3   | 0   |
| 4   | 6   | 3   |
| 7   | 2   | 27  |

4. #4, p.239, Atkinson

Graph the errors of the Taylor series approximations  $p_n(x)$  to  $f(x) = \sin[(\pi x/2)]$  on  $-1 \leq x \leq 1$ , for  $n = 1, 3, 5$ . Note the behavior of the error both near the origin and near the endpoints.

5. #5, p.240, Atkinson

Let  $f(x)$  be three times continuously differentiable on  $[-\alpha, \alpha]$  for some  $\alpha > 0$ , and consider approximating it by the rational function.

$$R(x) = \frac{a + bx}{1 + cx}$$

To generalize the idea of the Taylor series, choose the constants  $a, b$ , and  $c$  so that

$$R^{(j)}(0) = f^{(j)}(0), \quad j = 0, 1, 2$$

Is it always possible to find such an approximation  $R(x)$ ? The function  $R(x)$  is an example of a *Pade approximation* to  $f(x)$ . See Baker (1975) and Brezinski (1980).
